ABSTRACT

Water is essential for all living beings, making the preservation of existing sources crucial to addressing water scarcity. However, many water sources are polluted or saline, making them unsuitable for drinking. Converting saline water into fresh water is vital for future demand management. A solar still (SS) based desalination system effectively transforms polluted water into potable water, but traditional systems suffer from low efficiency due to less evaporation and condensation rate. This study proposes a hybrid PV/T (photovoltaic/thermal) system contains conventional SS with a metal scraper (CSSMS), double fan (CSSDF), and both combined (CSSMSDF). The obtained results reveals that the hybrid PV/T system integrated with CSSMSDF exhibits superior performance compared to the other cases, achieving minimum distillation production cost of 0.011 \$/L, maximum annual water yield of 948.663 L/m², payback period of 1.77 years (for energy) and 25.04 years (for exergy). Specifically, it achieves additional energy/exergy efficiency of (8.99 %, 0.52 %) over CSS, (7.69 %, 0.44 %) over CSSMS and (1.04 %, 0.008 %) over CSSDF.

1. Introduction

Water is an important and basic source for the survival of every human. Statistical data reveal that nearly 70 % Earth's surface is dominated by water. Its resource may be either naturally present or produced through human activities. The water that produced naturally is either freshwater or saline water that depends on the salinity level. In the world water resources, 96.5 % of world water is found in the oceans and seas with average salinity of 350 ppm, where ice caps shared 1.7 %, underground in aquifers is shared 1.6 %, and rivers & lakes shared only 0.015 %. The freshwater is naturally renewable which are found in rivers, lakes and in underground aquifers. Aquifers hold the estimated volume of (10,530*1000) km³ followed by the lakes & rivers with 91,000 km³ and 2100 km³ respectively. This water is used to serves various purposes with direct human consumption of 10–12 %, 15 % for irrigation and 70–75 % for agriculture purposes. The consumption of freshwater is higher its natural recharge rates. Although the surface water is common, it represents only 0.27 % of fresh water. Due to

industrialization, urbanization the resources for water are increasingly polluted and leads to water scarcity [1,2]. So, it is most significant to get potable drinking water by converting polluted water for managing the demand of freshwater.

Desalination [3] is the process that take out the minerals and dissolved salts from the seawater or brackish water, thereby making it suitable for drinking with a parts per million of less than 500. The conventional desalination methods like vapor compression, humidification, dehumidification, ion exchange, electro dialysis, thin-film desalination and reverse osmosis are found to be complex and expensive process. Solar [4,5] still based desalination [6,7] has gained attraction in the arid areas which have abundant sunshine duration and scarce for fresh water. In SS, water is left in a container which is in open condition to evaporate and reach the air form. SS is functions to capture the evaporated water and condense it on the cold surface. The sluggish evaporation process of pure water leads for leaving whole contaminants within the system. The major benefits of solar stills [8] are, it is reliable system, low cost, simple maintenance and less environmental impact. Meanwhile, its drawback is the low conversion efficiency and
